# Agenda

---

- Expressions
- Operator Types
- Arithmetic Operators
- Assignment Operators
- Increment / Decrement Operators
- Logical Operators
- Comparison Operators
- Operator Precedence
- Type Conversion

# Operators, Operands and Expressions

An expression is a sequence of *operators* and their *operands*, that specifies a computation.

<http://en.cppreference.com/w/cpp/language/expressions>

Every expression yields a result.

```
2 + 3;  
"C++";  
x = 42;  
std::cout << "Hello World";  
C++;  
;  
;
```

Operator  
Operands

←  
null statement

# Operator Types

## Unary operator – one operand

`~expr`

`&expr`

`expr--`

`+expr`

## Binary operator – two operands

`expr1 = expr2`

`expr1 - expr2`

`expr1 | expr2`

`expr1 < expr2`

## Ternary operator - three operands (guess which one?)

# Arithmetic Operators

<code>+a</code>	unary plus
<code>-a</code>	unary minus
<code>a * b</code>	multiplication
<code>a / b</code>	division
<code>a % b</code>	modulo
<code>a + b</code>	addition
<code>a - b</code>	subtraction

- Can be applied to any of the arithmetic types
- They group left to right if precedence levels are same

```
int i;  
i = j * k / l;           // All operators have same precedence  
i = ((j * k) / l);       // The order of evaluation, left to right
```

# Arithmetic Operators

<code>~a</code>	bitwise NOT
<code>a &lt;&lt; b</code>	left shift
<code>a &gt;&gt; b</code>	right shift
<code>a &amp; b</code>	bitwise AND
<code>a ^ b</code>	bitwise XOR
<code>a   b</code>	bitwise OR

## Bitwise operators

- Operands are of integral type
- Operators work on the bit level
- Recommend to work on unsigned values

# Assignment Operators

=      assignment

The left hand operand must be a nonconst lvalue

```
int i, j;  
1024 = i;      // Error: Literals are lvalues  
i + j = 512;   // Error: Expressions are lvalues  
i = 256;      // OK
```

lvalue : An object that persists beyond the expression

rvalue : A temporary value that does not persist after the expression

Only lvalues can be on the left side of assignment  
lvalues and rvalues can be on the right side

# Compound Assignment Operators

<code>a += b</code>	addition assignment
<code>a -= b</code>	subtraction assignment
<code>a *= b</code>	multiplication assignment
<code>a /= b</code>	division assignment
<code>a %= b</code>	modulo assignment
<code>a &amp;= b</code>	bitwise AND assignment
<code>a  = b</code>	bitwise OR assignment
<code>a ^= b</code>	bitwise XOR assignment
<code>a &lt;&lt;= b</code>	bitwise left shift assignment
<code>a &gt;&gt;= b</code>	bitwise right shift assignment

## Shortcut to do operation and assignment

```
int i;  
i = i + 1;    // Add 1 to i, and assign the result back to i  
i += 1;      // Same as above
```

# Increment / Decrement Operators

<code>++a</code>	pre-increment
<code>--a</code>	pre-decrement
<code>a++</code>	post-increment
<code>a--</code>	post-decrement

## Shortcut for adding or subtracting by 1

```
int i = 0, j;  
j = ++i;           // i = 1, j = 1. Incremented value is assigned  
j = i++;           // i = 2, j = 1. unincremented value is assigned
```

Prefix returns changed value

Postfix returns unchanged copy of the value. Hence we don't use postfix on objects, as it performs unnecessary copying.

**tl;dr - Use prefix, always.**

# Logical Operators

<code>!a</code>	Negation
<code>a &amp;&amp; b</code>	AND
<code>a    b</code>	Inclusive OR

Returns values of type `bool` (true or false)  
0 is false, true otherwise

```
0        // False
'0'      // True: '0' is not a zero, has value of 48
1        // True: non-zero
'\0'     // False: \0 is a zero value
-1       // True: non-zero
```

# Logical Operators

- ! (Not) Operator

<code>&lt;expr&gt;</code>	<code>!&lt;expr&gt;</code>
true (nonzero)	false (0)
false (0)	true (1)

# Logical Operators

- && (And) Operator

<expr1>	<expr2>	<expr1> && <expr2>
false	false	false
false	true	false
true	false	false
true	true	true

# Logical Operators

- || (Or) Operator

<expr1>	<expr2>	<expr1>    <expr2>
false	false	false
false	true	true
true	false	true
true	true	true

# Logical Operators

AND and OR operators evaluate left operand first

- If left operand determines result, right operand is not evaluated
- Short-circuit (Lazy) Evaluation

expr1 || expr2

NOPE! If expr1 is true

expr1 && expr2

NOPE! If expr1 is false

Programmer's girlfriend -

"Are you going to sit and type in front of that thing all day or are you going out with me?"

Programmer - "Yes"

# Comparison Operators

<code>a == b</code>	Equal to
<code>a != b</code>	Not equal to
<code>a &lt; b</code>	Smaller than
<code>a &gt; b</code>	Greater than
<code>a &lt;= b</code>	Smaller than or equal to
<code>a &gt;= b</code>	Greater than or equal to

Returns values of type `bool` (true or false)

They do not chain together

```
int i = 50;  
10 < i < 20;           // Check if i is between 10 and 20  
(10 < 50) < 20        // Order of evaluation, left associative  
(1 < 20)               // True result, converted to int  
1                      // Expression returns true
```

Don't be lazy, do it properly

```
(10 < i) and (i < 50)
```

# Comparison Operators

Do not confuse `==` with `=`

`==` is comparison

`=` is assignment

```
int i = 0, j = 10;  
i == j;           // Returns false, 0 is not 10  
i = j;            // Returns true, i has a value of 10
```

# Operator Precedence

<code>+ - (unary) !</code>
<code>* / %</code>
<code>+ - (addition, subtraction)</code>
<code>&lt; &lt;= &gt;= &gt;</code>
<code>== !=</code>
<code>&amp;&amp;</code>
<code>  </code>
<code>=</code>

Order of evaluation

The list is much bigger than this. Go look it up

# Operator Precedence

Operators with higher precedence gets evaluated first

$$\begin{array}{c} 4 / 3 + 2 \\ (4 / 3) + 2 \end{array}$$

$$\begin{array}{c} -26 / (26/2) + 45 * 3/5 \\ (((-26) / (26/2)) + ((45 * 3)/5)) \end{array}$$

Parentheses override precedence

Why does the assignment operator have a low precedence?

# Type Conversion

## Implicit type conversion

<code>5 / 2</code> returns <code>2</code>	<code>int / int</code> returns <code>int</code>
<code>5.0f / 2</code> returns <code>2.5f</code>	<code>float / int</code> returns <code>float</code>
<code>5 / 2.0f</code> returns <code>2.5f</code>	<code>int / float</code> returns <code>float</code>

The integer is promoted to the same data type before evaluation.  
Data types are always promoted to a higher precision.

## Explicit type conversion

`static_cast<float> (5) / 2` returns `2.5f`  
`(float) 5 / 2` returns `2.5f`    **Old way of conversion**

Convert one or both of the operands to a higher precision in order to get the precision you need.
